

# The Set Mappings Generating Geometry and Physics

George. M. Van Treeck

**ABSTRACT.** Countable distance and volume set mappings between sets of size  $c$  subintervals of domain and range intervals generate the properties of metric space, the  $L_p$  norms (for example, Manhattan and Euclidean distance), and the volume equation as  $c$  goes to zero. The volume proof is used to derive Newton's gravity force and Coulomb's charge force equations without using the inverse square law or Gauss's divergence theorem. The gravity and charge force derivations expose a proportionate interval principle that allows simple derivations of the inverse square law, spacetime, and general relativity equations. A symmetry constraint on totally ordered sets can limit distance and volume to 3 dimensions. All proofs are verified in Coq.

## 1. Introduction

The definitions of metric space, Euclidean distance, and area/volume in analysis [Gol76] [Rud76] are empirical models of Euclidean geometry [Joy98]. Deductive proofs that those definitions are derived from a set and limit-based foundation exposes properties of geometry that empirical modeling cannot provide, for example: the counting constraint between the infinitesimal members of domain and range sets that makes a space flat; the countable domain-to-range set mapping that makes Euclidean distance the smallest possible distance in flat space; the set operation and constraint generating the properties of metric space; and the symmetry constraint on totally ordered sets that can limit distance and volume to 3 dimensions.

A definition of a dimension is where each countable domain set,  $x_i$ , has a corresponding range set,  $y_i$ . The countable distance spanning the domain sets is the cardinal of a constrained union of the range (distance) sets,  $d_c = |\bigcup_{i=1}^n y_i|$ , where vertical bars around a set,  $|\{\dots\}|$ , or list,  $[[\dots]]$ , indicates the cardinal (the number of members in the set or list). As the intersection of the range sets increases, more domain set members can map to a single range set member. Therefore, the cardinal of a constrained union range set,  $d_c$ , is a function of a constrained number of domain-to-range set mappings. Countable volume is the cardinal of the set of all possible countable distance unions, which is function of the number of distance-to-distance (range-to-range) set mappings.

Applying these abstract, countable set definitions of distance and volume to sets of size  $c$  subintervals of domain and range intervals generates the properties of metric space, all  $L_p$  norms (Minkowski distances, for example, Manhattan and Euclidean distance), and the volume equation as  $c \rightarrow 0$ .

The volume proof is used to derive Newton's gravity force and Coulomb's charge force equations without using the inverse square law or Gauss's divergence theorem. The gravity and charge force derivations expose a proportionate interval principle that allows simple derivations of the inverse square law, spacetime, and some general relativity equations.

All the proofs in this article have been verified using using the Coq proof verification system [Coq15]. The formal proofs are in the Coq files, "euclidrelations.v" and "threed.v," at: <https://github.com/treeck/RASRGeometry>.

## 2. Ruler measure and convergence

A tool is needed to derive geometric relations from the number of possible mappings between the  $p_x$  number of size  $c$  subintervals in one interval and the  $p_y$  number of size  $c$  subintervals in another interval. A ruler (measuring stick) measures the size of each interval *approximately* as the sum of the nearest integer number,  $p$ , of whole subintervals, where each subinterval has the *same* size,  $c$ .

**DEFINITION 2.1.** Ruler measure,  $M$ :  $\forall c, s \in \mathbb{R}, [a, b] \subset \mathbb{R}, s = b - a \wedge c > 0 \wedge (p = \text{floor}(s/c) \vee p = \text{ceiling}(s/c)) \wedge M = \sum_{i=1}^p c = pc$ .

**THEOREM 2.2.** *Ruler convergence:*  $M = \lim_{c \rightarrow 0} pc = s$ .

The proof is trivial but is included here for completeness. The theorem, "limit\_c\_0\_M.eq\_exact\_size," and formal proof is in the Coq file, euclidrelations.v.

**PROOF.** (epsilon-delta proof)

By definition of the floor function,  $\text{floor}(x) = \max(\{y : y \leq x, y \in \mathbb{Z}, x \in \mathbb{R}\})$ :

$$(2.1) \quad \forall c > 0, p = \text{floor}(s/c) \wedge 0 \leq |\text{floor}(s/c) - s/c| < 1 \Rightarrow 0 \leq |p - s/c| < 1.$$

Multiply all sides of inequality 2.1 by  $c$ :

$$(2.2) \quad \forall c > 0, \quad 0 \leq |p - s/c| < 1 \Rightarrow 0 \leq |pc - s| < |c|.$$

$$(2.3) \quad \forall \delta : |pc - s| < |c| = |c - 0| < \delta \\ \Rightarrow \quad \forall \epsilon = \delta : |c - 0| < \delta \wedge |pc - s| < \epsilon := M = \lim_{c \rightarrow 0} pc = s. \quad \square$$

The following is an example of ruler convergence for the interval,  $[0, \pi]$ :  $s = \pi - 0$ , and  $p = \text{floor}(s/c) \Rightarrow p \cdot c = 3.1_{c=10^{-1}}, 3.14_{c=10^{-2}}, 3.141_{c=10^{-3}}, \dots, \pi_{\lim_{c \rightarrow 0}}$ .

### 3. Distance

**3.1. Countable distance.** Each disjoint domain set,  $x_i$ , has its own range (distance) set,  $y_i$ . The countable distance spanning the disjoint domain sets is the cardinal,  $d_c$ , of a union range (distance) set that is constrained by a relation between the number of members in the domain set and corresponding range set.

It will be shown in the next subsections that the constraint,  $|x_i| = |y_i|$ , generates Manhattan and Euclidean distance at the boundaries (generates flat space/rectilinear distances). Generalizing distance and volume beyond flat space is shown in the last section of this article.

DEFINITION 3.1. Countable distance,  $d_c$ , in flat space:

$$d_c = |\bigcup_{i=1}^n y_i| : \bigcap_{i=1}^n x_i = \emptyset \quad \wedge \quad |x_i| = |y_i|.$$

**3.2. Union-Sum Inequality.** The inequality,  $|\bigcup_{i=1}^n y_i| \leq \sum_{i=1}^n |y_i|$ , is used in this article. The proof is trivial but is included here for completeness.

The proof follows from the associative law of addition where the sum of set sizes is equal to the size of all the set members appended into a list and the commutative law of addition that allows sorting that list into a list of unique members (the *union* set) and a list of duplicates. For example,  $y_1 = \{a, b, c\}$  and  $y_2 = \{c, d, e\} \Rightarrow \bigcup_{i=1}^2 |y_i| = |\{a, b, c, d, e\}| = 5 < \sum_{i=1}^2 |y_i| = |\{a, b, c\}| + |\{c, d, e\}| = |\{a, b, c, c, d, e\}| = |\{a, b, c, d, e\}| + |[c]| = 6$ .

LEMMA 3.2. *Union-Sum Inequality:*  $|\bigcup_{i=1}^n y_i| \leq \sum_{i=1}^n |y_i|$ .

PROOF. A formal proof, `union_sum_inequality`, using sorting into a set of unique members (*union* set) and a list of duplicates, is in the file `euclidrelations.v`.

$$(3.1) \quad \sum_{i=1}^n |y_i| = |\text{append}_{i=1}^n y_i| = |\text{sort}(\text{append}_{i=1}^n y_i)| \\ = |\bigcup_{i=1}^n y_i| + |\text{duplicates}_{i=1}^n y_i|.$$

$$(3.2) \quad |\bigcup_{i=1}^n y_i| + |\text{duplicates}_{i=1}^n y_i| = \sum_{i=1}^n |y_i| \quad \wedge \quad |\text{duplicates}_{i=1}^n y_i| \geq 0 \\ \Rightarrow |\bigcup_{i=1}^n y_i| \leq \sum_{i=1}^n |y_i|. \quad \square$$

**3.3. Countable distance range.** From the countable distance constraint (3.1), where  $|x_i| = |y_i| = p_i$ , the countable distance,  $d_c$ , ranges from a function of the sum of 1-1 domain-to-range set correspondences,  $d_c = f(\sum_{i=1}^n (1 \cdot |y_i|)) = f(\sum_{i=1}^n p_i)$ , to a function of the sum of each-to-each (Cartesian product) domain-to-range set mappings,  $d_c = f(\sum_{i=1}^n (|x_i| \cdot |y_i|)) = f(\sum_{i=1}^n p_i^2)$ .

### 3.4. Manhattan distance.

THEOREM 3.3. *Manhattan (largest) distance,  $d$ , is the size of the range interval,  $[d_0, d_m]$ , corresponding to a set of disjoint domain intervals,  $\{[a_1, b_1], [a_2, b_2], \dots, [a_n, b_n]\}$ , where:*

$$d = \sum_{i=1}^n s_i, \quad d = d_m - d_0, \quad s_i = b_i - a_i.$$

The formal proof, “`taxicab_distance`,” is in the Coq file, `euclidrelations.v`.

PROOF.

From the countable distance definition (3.1) and the union-sum inequality (3.2), the largest possible countable distance,  $d_c$ , is the equality case:

$$(3.3) \quad d_c = |\bigcup_{i=1}^n y_i| \leq \sum_{i=1}^n |y_i| \wedge |x_i| = |y_i| = p_i \quad \Rightarrow \quad \exists p_i, d_c : d_c = \sum_{i=1}^n p_i.$$

Multiply both sides of equation 3.3 by  $c$  and take the limit:

$$(3.4) \quad d_c = \sum_{i=1}^n p_i \Rightarrow d_c \cdot c = \sum_{i=1}^n (p_i \cdot c) \Rightarrow \lim_{c \rightarrow 0} d_c \cdot c = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c).$$

Apply the ruler (2.1) and ruler convergence theorem (2.2) to the definition of  $d$ :

$$(3.5) \quad d = d_m - d_0 \Rightarrow \exists c d : \text{floor}(d/c) = d_c \Rightarrow d = \lim_{c \rightarrow 0} d_c \cdot c.$$

Apply the ruler (2.1) and ruler convergence theorem (2.2) to each domain interval:

$$(3.6) \quad s_i = b_i - a_i \quad \wedge \quad \text{floor}(s_i/c) = |x_i| = |y_i| = p_i \Rightarrow \lim_{c \rightarrow 0} p_i \cdot c = s_i.$$

Combine equations 3.5, 3.4, 3.6:

$$(3.7) \quad d = \lim_{c \rightarrow 0} d_c \cdot c \quad \wedge \quad \lim_{c \rightarrow 0} d_c \cdot c = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c) \quad \wedge \quad \lim_{c \rightarrow 0} (p_i \cdot c) = s_i \Rightarrow d = \lim_{c \rightarrow 0} d_c \cdot c = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c) = \sum_{i=1}^n s_i. \quad \square$$

### 3.5. Euclidean distance.

**THEOREM 3.4.** *Euclidean (smallest) distance,  $d$ , is the size of the range interval,  $[d_0, d_m]$ , corresponding to a set of disjoint domain intervals,  $\{[a_1, b_1], [a_2, b_2], \dots, [a_n, b_n]\}$ , where:*

$$d^2 = \sum_{i=1}^n s_i^2, \quad d = d_m - d_0, \quad s_i = b_i - a_i.$$

The formal proof, “Euclidean.distance,” is in the Coq file, euclidrelations.v.

**PROOF.**

Apply the rule of product to the largest number of domain-to-range set mappings, where all  $p_i$  number of range set members,  $y_i$ , map to each of the  $p_i$  number of members in the domain set,  $x_i$ , which, by the rule of product, is the Cartesian product,  $|y_i| \cdot |x_i|$ :

$$(3.8) \quad |x_i| = |y_i| = p_i \Rightarrow \sum_{i=1}^n |y_i| \cdot |x_i| = \sum_{i=1}^n p_i^2.$$

From the countable distance definition (3.1) and the union-sum inequality (3.2), the smallest possible distance is the equality case:

$$(3.9) \quad d_c = |\bigcup_{i=1}^n y_i| \leq \sum_{i=1}^n |y_i| \wedge |x_i| = |y_i| = p_i \Rightarrow \exists p_i, d_c : d_c = \sum_{i=1}^n p_i.$$

Square both sides of equation 3.9 ( $x = y \Leftrightarrow f(x) = f(y)$ ):

$$(3.10) \quad \exists p_i, d_c : d_c = \sum_{i=1}^n p_i \Leftrightarrow \exists p_i, d_c : d_c^2 = (\sum_{i=1}^n p_i)^2.$$

Apply the square of sum inequality,  $(\sum_{i=1}^n p_i)^2 \geq \sum_{i=1}^n p_i^2$ , to equation 3.10 and select the smallest area (the equality) case:

$$(3.11) \quad d_c^2 = (\sum_{i=1}^n p_i)^2 = \sum_{i=1}^n p_i \sum_{j=1}^n p_j \\ = \sum_{i=1}^n p_i^2 + \sum_{i=1}^n p_i \sum_{j=1, j \neq i}^n p_j \geq \sum_{i=1}^n p_i^2 \Rightarrow \exists p_i : d_c^2 = \sum_{i=1}^n p_i^2.$$

Multiply both sides of equation 3.11 by  $c^2$ , simplify, and take the limit.

$$(3.12) \quad d_c^2 = \sum_{i=1}^n p_i^2 \Rightarrow d_c^2 \cdot c^2 = \sum_{i=1}^n p_i^2 \cdot c^2 \Leftrightarrow (d_c \cdot c)^2 = \sum_{i=1}^n (p_i \cdot c)^2 \\ \Rightarrow \lim_{c \rightarrow 0} (d_c \cdot c)^2 = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c)^2.$$

Apply the ruler (2.1) and ruler convergence theorem (2.2) and square both sides:

$$(3.13) \quad \exists c d \in \mathbb{R} : \text{floor}(d/c) = d_c \Rightarrow d = \lim_{c \rightarrow 0} d_c \cdot c \Rightarrow d^2 = \lim_{c \rightarrow 0} (d_c \cdot c)^2.$$

Apply the ruler (2.1) and ruler convergence theorem (2.2) to each domain interval:

$$(3.14) \quad s_i = b_i - a_i \quad \wedge \quad \text{floor}(s_i/c) = |x_i| = |y_i| = p_i \Rightarrow \lim_{c \rightarrow 0} p_i \cdot c = s_i.$$

Combine equations 3.13, 3.12, 3.14:

$$(3.15) \quad d^2 = \lim_{c \rightarrow 0} (d_c \cdot c)^2 \quad \wedge \quad \lim_{c \rightarrow 0} (d_c \cdot c) = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c)^2 \quad \wedge \\ \lim_{c \rightarrow 0} (p_i \cdot c) = s_i \quad \Rightarrow \quad d^2 = \lim_{c \rightarrow 0} (d_c \cdot c)^2 = \sum_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c)^2 = \sum_{i=1}^n s_i^2. \quad \square$$

**3.6. Metric Space.** All distances,  $d(u, w)$ , satisfying the countable distance definition (3.1), where the ruler is applied, generates the properties of metric space. The formal proofs: triangle\_inequality, non\_negativity, identity\_of\_indiscernibles, and symmetry are in the Coq file, euclidrelations.v.

**THEOREM 3.5.** *Triangle Inequality:*  $d_c = |y_1 \cup y_2| \Rightarrow d(u, w) \leq d(u, v) + d(v, w)$ .

**PROOF.** Use the countable distance (3.1) and union-sum inequality (3.2) as conditions. And next apply the ruler measure (2.1) and ruler convergence (2.2).

$$(3.16) \quad \forall c > 0, d(u, w), d(u, v), d(v, w) : \\ |y_1| = \text{floor}(d(u, v)/c) \quad \wedge \quad |y_2| = \text{floor}(d(v, w)/c) \quad \wedge \\ d_c = \text{floor}(d(u, w)/c) \quad \wedge \quad d_c = |y_1 \cup y_2| \leq |y_1| + |y_2| \\ \Rightarrow \text{floor}(d(u, w)/c) \leq \text{floor}(d(u, v)/c) + \text{floor}(d(v, w)/c) \\ \Rightarrow \text{floor}(d(u, w)/c) \cdot c \leq \text{floor}(d(u, v)/c) \cdot c + \text{floor}(d(v, w)/c) \cdot c \\ \Rightarrow \lim_{c \rightarrow 0} \text{floor}(d(u, w)/c) \cdot c \leq \lim_{c \rightarrow 0} \text{floor}(d(u, v)/c) \cdot c + \lim_{c \rightarrow 0} \text{floor}(d(v, w)/c) \cdot c \\ = d(u, w) \leq d(u, v) + d(v, w). \quad \square$$

**THEOREM 3.6.** *Non-negativity:*  $d_c = |y_1 \cup y_2| \Rightarrow d(u, w) \geq 0$ .

**PROOF.** By definition, a set always has a size (cardinal)  $\geq 0$ :

$$(3.17) \quad \forall c > 0, d(u, w) : \text{floor}(d(u, w)/c) = d_c \quad \wedge \quad d_c = |y_1 \cup y_2| \geq 0 \\ \Rightarrow \text{floor}(d(u, w)/c) = d_c \geq 0 \quad \Rightarrow \quad d(u, w) = \lim_{c \rightarrow 0} d_c \cdot c \geq 0. \quad \square$$

**THEOREM 3.7.** *Identity of Indiscernibles:*  $d(w, w) = 0$ .

**PROOF.** Apply the triangle inequality property (3.5):

$$(3.18) \quad \forall d(u, v) = d(v, w) = 0 \quad \wedge \quad d(u, w) \leq d(u, v) + d(v, w) \quad \Rightarrow \quad d(u, w) \leq 0.$$

Combine the non-negativity property (3.6) and the previous inequality (3.18):

$$(3.19) \quad d(u, w) \geq 0 \quad \wedge \quad d(u, w) \leq 0 \quad \Leftrightarrow \quad 0 \leq d(u, w) \leq 0 \quad \Rightarrow \quad d(u, w) = 0.$$

Combine the result of step 3.19 and the condition,  $d(u, v) = 0$ , in step 3.18.

$$(3.20) \quad d(u, w) = 0 \quad \wedge \quad d(u, v) = 0 \quad \Rightarrow \quad w = v.$$

Combine the condition,  $d(v, w) = 0$ , in step 3.18 and the result of step 3.20.

$$(3.21) \quad d(v, w) = 0 \quad \wedge \quad w = v \quad \Rightarrow \quad d(w, w) = 0. \quad \square$$

**THEOREM 3.8.** *Symmetry:*  $d_c = |y_1 \cup y_2| \quad \wedge \quad |x_i| = |y_i| \quad \Rightarrow \quad d(u, v) = d(v, u)$ .

**PROOF.** The number domain set,  $x_i$ , members mapping to a range set,  $y_i$ , member increases with the amount of range set intersection. Therefore, the range of countable distances (3.3) is a function of domain-to-range set members, under the constraint,  $|x_i| = |y_i|$ , is:

$$(3.22) \quad |x_i| = |y_i| = p_i \quad \Rightarrow \quad d_c = f(\sum_{i=1}^n |x_i| \cdot |y_i|^q) = f(\sum_{i=1}^n p_i^{1+q}), \quad q \in \{0, 1\}.$$

Where  $d_c$  is applied to sets of size  $c$  subintervals of intervals, the previous Manhattan distance proof (3.3),  $d(x, y) = f(\sum_{i=1}^2 s_i^1)$ , and Euclidean distance proof (3.4),  $d(x, y) = f(\sum_{i=1}^2 s_i^2)$ , show that distance is a function of domain interval sizes,  $s_i$ , where  $x = s_1$  and  $y = s_2$ . Generalizing:

$$(3.23) \quad \forall p : p \geq 0, \quad d(x, y) = f(\sum_{i=1}^2 s_i^p) = f(x^p + y^p) \\ \Rightarrow \quad d(u, v) = f(u^p + v^p) = f(v^p + u^p) = d(v, u). \quad \square$$

#### 4. Euclidean Volume

$\mathbb{R}^n$ , the Lebesgue measure, Riemann integral, and Lebesgue integral define (assume) area/volume to be the product of domain interval lengths. The goal here is to derive the area/volume equation from an abstract, set-based definition of volume without assuming the product of interval lengths.

Countable volume is the cardinal of the set of all possible countable distance unions. Each possible union of a member of one distance (range) set is either an intersection or non-intersection with a member in each of the other range sets forming an  $n$ -tuple (Cartesian coordinate). By the rule of product, the total number of  $n$ -tuples (unions),  $v_c$ , is the Cartesian product of distance-to-distance (range-to-range) set mappings,  $v_c = |\times_{i=1}^n y_i|$ .

DEFINITION 4.1. Euclidean (largest possible) Countable Volume in flat space:

$$v_c = |\times_{i=1}^n y_i| = \prod_{i=1}^n |y_i| : \quad \bigcap_{i=1}^n x_i = \bigcap_{i=1}^n y_i = \emptyset \quad \wedge \quad |x_i| = |y_i|.$$

THEOREM 4.2. *Euclidean volume,  $v$ , is length of the range interval,  $[v_0, v_m]$ , equal to product of domain interval lengths,  $\{[a_1, b_1], [a_2, b_2], \dots, [a_n, b_n]\}$ :*

$$v = \prod_{i=1}^n s_i, \quad v = v_m - v_0, \quad s_i = b_i - a_i.$$

The formal proof, “Euclidean\_volume,” is in the Coq file, euclidrelations.v.

PROOF.

Use the ruler (2.1) to partition each of the domain intervals,  $[a_i, b_i]$ , into a set,  $x_i$ , containing  $p_i$  number of subintervals.

$$(4.1) \quad \forall i \ n \in \mathbb{N}, \quad i \in [1, n], \quad c > 0 \quad \wedge \quad \text{floor}(s_i/c) = p_i = |x_i| = |y_i|.$$

Apply the ruler convergence theorem (2.2) to equation 4.1:

$$(4.2) \quad \text{floor}(s_i/c) = p_i \quad \Rightarrow \quad \lim_{c \rightarrow 0} (p_i \cdot c) = s_i.$$

$$(4.3) \quad v_c = \prod_{i=1}^n |y_i| \quad \wedge \quad |y_i| = p_i \quad \Rightarrow \quad v_c = \prod_{i=1}^n p_i.$$

Multiply both sides of equation 4.3 by  $c^n$ :

$$(4.4) \quad v_c \cdot c^n = (\prod_{i=1}^n p_i) \cdot c^n = \prod_{i=1}^n (p_i \cdot c).$$

Apply the ruler (2.1) to the range interval,  $[v_0, v_m]$  (where  $v = v_m - v_0$ ). Combine with equation 4.4. Apply the ruler convergence (2.2) and equation 4.2.

$$(4.5) \quad \forall v_c, n \in \mathbb{N}, \quad c > 0 \exists v \in \mathbb{R} : \text{floor}(v/c^n) = v_c \quad \wedge \quad v_c \cdot c^n = \prod_{i=1}^n (p_i \cdot c) \\ \Rightarrow \quad v = \lim_{c \rightarrow 0} v_c \cdot c^n = \prod_{i=1}^n \lim_{c \rightarrow 0} (p_i \cdot c) = \prod_{i=1}^n s_i. \quad \square$$

## 5. Applications to physics

**5.1. Newton's gravity force equation.**  $m_1$  and  $m_2$ , are the sizes of two independent mass intervals, where each size  $c$  subinterval of a mass interval exerts a force on each size  $c$  subinterval of the other mass interval. If  $p_1$  and  $p_2$  are the number of size  $c$  components in each mass interval, then the total force,  $F$ , is equal to the total number of forces, which is proportionate to the Cartesian product,  $p_1 \cdot p_2$ , and proportionate to the size,  $c$ , of each component. Applying the volume proof (4.2), the total size of the Cartesian product of size  $c$  components is  $p_1 c \cdot p_2 c$ .

$$(5.1) \quad p_1 = \text{floor}(m_1/c) \quad \wedge \quad p_2 = \text{floor}(m_2/c) \quad \wedge \quad F := m_0 a \propto p_1 c \cdot p_2 c \\ \Rightarrow \quad F := m_0 a \propto \left( \lim_{c \rightarrow 0} p_1 c \cdot \lim_{c \rightarrow 0} p_2 c \right) = m_1 m_2,$$

where the force,  $F$ , is defined as the rest mass,  $m_0$ , times acceleration,  $a$ .

$$(5.2) \quad F := m_0 a = m_0 r / t_c^2 \propto m_1 m_2 \quad \wedge \quad m_0 = m_1 \quad \Rightarrow \quad r \propto m_1 \quad \Rightarrow \\ \exists m_G, r_c \in \mathbb{R} : r = (r_c / m_G) m_2,$$

where:  $r$  is Euclidean distance,  $t_c$  is a unit of time, and  $r_c / m_G$  is a unit-factoring proportion ratio.

$$(5.3) \quad F := m_0 a = m_0 r / t_c^2 \propto m_1 m_2 \quad \wedge \quad m_0 = m_1 \quad \Rightarrow \quad r \propto m_1 \quad \Rightarrow \\ \exists m_G, r_c \in \mathbb{R} : r = (r_c / m_G) m_2,$$

where  $r_c / m_G$  is a unit-factoring proportion ratio.

$$(5.4) \quad m_0 = m_1 \quad \wedge \quad r = (m_G / r_c) m_2 \quad \wedge \quad F := m_0 a = m_0 r / t_c^2 \\ \Rightarrow \quad F := m_0 a = m_0 r / t_c^2 = (r_c / m_G) m_1 m_2 / t_c^2.$$

From equation (5.2):

$$(5.5) \quad \exists t_c, r_c \in \mathbb{R} \quad \Rightarrow \quad \exists t \in \mathbb{R} : t = (t_c / r_c) r.$$

$$(5.6) \quad t = (t_c / r_c) r \quad \wedge \quad F := m_0 a = (r_c / m_G) m_1 m_2 / t_c^2 \quad \Rightarrow \\ F := m_0 a = (r_c / m_G) (r_c^2 / t_c^2) m_1 m_2 / r^2 = (r_c^3 / m_G t_c^2) m_1 m_2 / r^2 = G m_1 m_2 / r^2,$$

where the gravitational constant,  $G = r_c^3 / m_G t_c^2$ , has the SI units:  $m^3 kg^{-1} s^{-2}$ .

**5.2. Coulomb's charge force.**  $q_1$  and  $q_2$ , are the sizes of two independent charge intervals, where each size  $c$  subinterval of a charge interval exerts a force on each size  $c$  subinterval of the other charge interval. If  $p_1$  and  $p_2$  are the number of size  $c$  components in each charge interval, then the total force,  $F$ , is equal to the total number of forces, which is proportionate to the Cartesian product,  $p_1 \cdot p_2$ , and the size,  $c$ , of each component. Applying the volume proof (4.2), the total size of the Cartesian product of size  $c$  components is  $p_1 c \cdot p_2 c$ .

$$(5.7) \quad p_1 = \text{floor}(q_1/c) \quad \wedge \quad p_2 = \text{floor}(q_2/c) \quad \wedge \quad F \propto p_1 c \cdot p_2 c \\ \Rightarrow \quad F := m_0 a \propto \left( \lim_{c \rightarrow 0} p_1 c \cdot \lim_{c \rightarrow 0} p_2 c \right) = (q_1 q_2),$$

where the force,  $F$ , is defined as the rest mass,  $m_0$ , times acceleration,  $a$ .

$$(5.8) \quad F := m_0 a = m_0 r / t_c^2 \propto q_1 q_2 \quad \wedge \quad m_0 = (m_C / q_C) q_1 \quad \Rightarrow \quad r \propto q_1 \quad \Rightarrow \\ \exists q_C, r_c \in \mathbb{R} : r = (r_c / q_C) q_2,$$

where:  $r$  is Euclidean distance,  $t_c$  is a unit of time,  $m_C/q_C$  and  $q_C/r_c$  are unit-factoring proportion ratios.

$$(5.9) \quad m_0 = (m_C/q_C)q_1 \quad \wedge \quad r = (q_C/r_c)q_2 \quad \wedge \quad F := m_0a = m_0r/t_c^2 \\ \Rightarrow \quad F := m_0a = m_0r/t_c^2 = (m_C/q_C)(r_c/q_C)q_1q_2/t_c^2 = (m_Cr_c/q_C^2)q_1q_2/t_c^2.$$

From equation (5.8):

$$(5.10) \quad \exists t_c, r_c \in \mathbb{R} \quad \Rightarrow \quad \exists t \in \mathbb{R} : t = (t_c/r_c)r.$$

$$(5.11) \quad t = (t_c/r_c)r \quad \wedge \quad a_C = r_c/t_c^2 \quad \wedge \quad F := m_0a = (m_Cr_c/q_C^2)q_1q_2/t_c^2 \Rightarrow \\ F := m_0a = (r_c^2/t_c^2)(m_Cr_c/q_C^2)q_1q_2/r^2 = ((m_Ca_C)r_c^2/q_C^2)q_1q_2/r^2 = k_Cq_1q_2/r^2,$$

where the charge constant,  $k_C = (m_Ca_C)r_c^2/q_C^2$ , has the SI units:  $Nm^2C^{-2}$ .

**5.3. Spacetime equations.** As shown in the derivations of Newton's gravity force (5.1) and Coulomb's charge force (5.2) equations, for any Euclidean distance interval having size,  $r$ , an interval having size,  $t$ , exists, where  $r = (r_c/t_c)t = ct$ , and  $r_c/t_c = c$  is a unit-factoring proportion ratio.

Applying the ruler to two intervals,  $[0, r_1]$  and  $[0, r_2]$ , in two inertial (independent, non-accelerating) frames of reference, the smallest distance (and time) spanning the two intervals converges to the Euclidean distance (3.4),  $r$ .

$$(5.12) \quad r^2 = r_1^2 + r_2^2 \quad \wedge \quad r = (r_c/t_c)t = ct \quad \Rightarrow \quad (ct)^2 = r_1^2 + r_2^2 \\ \Leftrightarrow \quad r_1^2 = (ct)^2 - (x^2 + y^2 + z^2),$$

where  $r_2^2 = x^2 + y^2 + z^2$ , which is one form of Minkowski's flat spacetime interval equation [Bru17]. And the length contraction and time dilation equations also follow directly from  $(ct)^2 = r_1^2 + r_2^2$ , where  $v = r_1/t$ :

$$(5.13) \quad r_2^2 = c^2t^2 - r_1^2 \quad \wedge \quad r' = r_2 \quad \Rightarrow \quad r'^2/t^2 = c^2 - v^2 \quad \Rightarrow \quad r' = ct\sqrt{1 - (v/c)^2} \\ \Rightarrow \quad r' = ct\sqrt{1 - (v/c)^2} \quad \wedge \quad r = ct \quad \Rightarrow \quad r' = r\sqrt{1 - (v/c)^2}.$$

$$(5.14) \quad r' = ct\sqrt{1 - (v/c)^2} \quad \wedge \quad t' = r'/c \quad \Rightarrow \quad t = t'/\sqrt{1 - (v/c)^2}.$$

**5.4. Some general relativity without the complexity of tensors:** Using the mass and spacetime ratios (first derivative equations):  $r = (r_c/m_G)m = ct \Rightarrow (r_c/m_G)m \cdot ct = r^2 \Rightarrow m = (m_G/r_c)r^2/t = (m_G/r_c)rv$ . For a constant mass,  $m$ , a decrease in the distance,  $r$ , between two mass centers causes a decrease in time,  $t$ , (time slows down).  $v$  is the relativistic orbital velocity at distance,  $r$ .  $E = mc^2 = (m_G/r_c)r^3/t^2$ . And  $KE = mv^2/2 = (m_Gc^2/2r_c)r$ . Likewise, for charge,  $r = (r_c/q_C)q = ct \Rightarrow q = (q_C/r_c)r^2/t = (q_C/r_c)rv$ ,  $E = qc^2 = (q_C/r_c)r^3/t^2$ , and  $KE = qv^2/2 = (q_Cc^2/2r_c)r$ . And so on.

**5.5. 3 dimensional balls.** Countable distance,  $d_c = |\bigcup_{i=1}^n y_i|$ , (3.1), countable volume,  $v_c = \prod_{i=1}^n |y_i|$ , (4.1), Manhattan distance (3.3), Euclidean distance (3.4), and volume (4.2) requires that a set of intervals/dimensions can be assigned a *total order* ( $i = 1$  to  $n$ ). And the commutative properties of union, multiplication, and addition allow sequencing through each interval (dimension) in every possible order. Sequencing (no jumping over other members) via the successor and predecessor relations of a totally ordered set in every possible order requires each

set member to be sequentially adjacent (either a successor or predecessor) to every other member, herein referred to as a symmetry constraint.

It will now be proved that coexistence of the symmetry constraint on a sequentially ordered set defines a cyclic set that contains at most 3 members, in this case, 3 dimensions of ordered and symmetric distance and volume.

DEFINITION 5.1. Ordered geometry:

$$\forall i \ n \in \mathbb{N}, \ i \in [1, n-1], \ \forall x_i \in \{x_1, \dots, x_n\}, \\ \text{successor } x_i = x_{i+1} \ \wedge \ \text{predecessor } x_{i+1} = x_i.$$

DEFINITION 5.2. Symmetry Constraint (every set member is sequentially adjacent to every other member):

$$\forall i \ j \ n \in \mathbb{N}, \ \forall x_i \ x_j \in \{x_1, \dots, x_n\}, \ \text{successor } x_i = x_j \Leftrightarrow \text{predecessor } x_j = x_i.$$

THEOREM 5.3. *An ordered and symmetric set is a cyclic set.*

$$i = n \ \wedge \ j = 1 \ \Rightarrow \ \text{successor } x_n = x_1 \ \wedge \ \text{predecessor } x_1 = x_n.$$

The formal proof, “ordered\_symmetric\_is\_cyclic,” is in the Coq file, threaded.v.

PROOF. A total order (5.1) defines unique successors and predecessors for all set members except for the successor of  $x_n$  and the predecessor of  $x_1$ . Therefore, the only member that can be a successor of  $x_n$ , without creating a contradiction, is  $x_1$ . And the only member that can be a predecessor of  $x_1$ , without creating a contradiction, is  $x_n$ . Applying the symmetry constraint (5.2):

$$(5.15) \quad i = n \ \wedge \ j = 1 \ \wedge \ \text{successor } x_i = x_j \ \Rightarrow \ \text{successor } x_n = x_1.$$

Applying the definition of the symmetry constraint (5.2) to conclusion 5.15:

$$(5.16) \quad \text{successor } x_i = x_j \ \Rightarrow \ \text{predecessor } x_j = x_i \ \Rightarrow \ \text{predecessor } x_1 = x_n. \quad \square$$

THEOREM 5.4. *An ordered and symmetric set is limited to at most 3 members.*

The lemmas and formal proofs in the Coq file threaded.v are:

Lemmas: adj111, adj122, adj212, adj123, adj133, adj233, adj213, adj313, adj323, and not\_all\_mutually\_adjacent\_gt\_3.

The following proof uses Horn clauses (a subset of first order logic) that uses unification and resolution. Horn clauses make it clear which facts satisfy a proof goal.

PROOF.

It was proved that an ordered and symmetric set is a cyclic set (5.3).

DEFINITION 5.5. Successor of  $m$  is  $n$ :

$$(5.17) \quad \text{Successor}(m, n, \text{setsize}) \leftarrow (m = \text{setsize} \wedge n = 1) \vee (n = m + 1 \leq \text{setsize}).$$

DEFINITION 5.6. Predecessor of  $m$  is  $n$ :

$$(5.18) \quad \text{Predecessor}(m, n, \text{setsize}) \leftarrow (m = 1 \wedge n = \text{setsize}) \vee (n = m - q \geq 1).$$

DEFINITION 5.7. Adjacent: member  $m$  is sequentially adjacent to member  $n$  if the successor of  $m$  is  $n$  or the predecessor of  $m$  is  $n$ . Notionally:

$$(5.19) \quad \text{Adjacent}(m, n, \text{setsize}) \leftarrow \text{Successor}(m, n, \text{setsize}) \vee \text{Predecessor}(m, n, \text{setsize}).$$

Prove that every member is adjacent to every other member, where  $setsize \in \{1, 2, 3\}$ :

$$(5.20) \quad \text{Adjacent}(1, 1, 1) \leftarrow \text{Successor}(1, 1, 1) \leftarrow (m = setsize \wedge n = 1).$$

$$(5.21) \quad \text{Adjacent}(1, 2, 2) \leftarrow \text{Successor}(1, 2, 2) \leftarrow (n = m + 1 \leq setsize).$$

$$(5.22) \quad \text{Adjacent}(2, 1, 2) \leftarrow \text{Successor}(2, 1, 2) \leftarrow (n = setsize \wedge m = 1).$$

$$(5.23) \quad \text{Adjacent}(1, 2, 3) \leftarrow \text{Successor}(1, 2, 3) \leftarrow (n = m + 1 \leq setsize).$$

$$(5.24) \quad \text{Adjacent}(2, 1, 3) \leftarrow \text{Predecessor}(2, 1, 3) \leftarrow (n = m - q \geq 1).$$

$$(5.25) \quad \text{Adjacent}(3, 1, 3) \leftarrow \text{Successor}(3, 1, 3) \leftarrow (n = setsize \wedge m = 1).$$

$$(5.26) \quad \text{Adjacent}(1, 3, 3) \leftarrow \text{Predecessor}(1, 3, 3) \leftarrow (m = 1 \wedge n = setsize).$$

$$(5.27) \quad \text{Adjacent}(2, 3, 3) \leftarrow \text{Successor}(2, 3, 3) \leftarrow (n = m + 1 \leq setsize).$$

$$(5.28) \quad \text{Adjacent}(3, 2, 3) \leftarrow \text{Predecessor}(3, 2, 3) \leftarrow (n = m - q \geq 1).$$

Must prove that for all  $setsize > 3$ , there exist non-adjacent members. For example, the first and third members are not  $(-)$  adjacent:

$$(5.29) \quad \forall setsize > 3 : \quad \neg \text{Successor}(1, 3, setsize > 3) \\ \leftarrow \text{Successor}(1, 2, setsize > 3) \leftarrow (n = m + 1 \leq setsize).$$

That is, member 2 is the only successor of member 1 for all  $setsize > 3$ , which implies member 3 is not a successor of member 1 for all  $setsize > 3$ .

$$(5.30) \quad \forall setsize > 3 : \quad \neg \text{Predecessor}(1, 3, setsize > 3) \\ \leftarrow \text{Predecessor}(1, setsize, setsize > 3) \leftarrow (m = 1 \wedge n = setsize > 3).$$

That is, member  $n = setsize > 3$  is the only predecessor of member 1, which implies member 3 is not a predecessor of member 1 for all  $setsize > 3$ .

$$(5.31) \quad \forall setsize > 3 : \quad \neg \text{Adjacent}(1, 3, setsize > 3) \\ \leftarrow \neg \text{Successor}(1, 3, setsize > 3) \wedge \neg \text{Predecessor}(1, 3, setsize > 3). \quad \square$$

That is, for all  $setsize > 3$ , some elements are not sequentially adjacent to every other element (not symmetric).

## 6. Insights and implications

- (1) The Manhattan and Euclidean distance proofs (3.3) (3.4) and the Euclidean volume proof (4.2) show the constraint that each domain set has a corresponding range (distance) set containing the same number of members,  $|x_i| = |y_i|$ , generates flat space (rectilinear distances and volume).
- (2) Generalizing the flat space constraint on countable distance and volume,  $|x_i| = |y_i|$ , to  $|x_i| = |y_i|^q$ ,  $q \geq 0$ , generates all the  $L^p$  norms (Minkowski distances),  $\|L\|_p = (\sum_{i=1}^n s_i^p)^{1/p}$ . For example, using the same proof pattern as for Euclidean distance (3.4):  $|y_i| = p_i \Rightarrow |x_i| = p_i^q \Rightarrow \sum_{i=1}^n |x_i| \cdot |y_i| = \sum_{i=1}^n p_i^q \cdot p_i = \sum_{i=1}^n p_i^{q+1} \leq d_c^{q+1}$ . Choosing the equality case and applying the ruler:  $d^{q+1} = \sum_{i=1}^n s_i^{q+1}$ . And  $p = q + 1 \Rightarrow d^p = \sum_{i=1}^n s_i^p \Rightarrow d = (\sum_{i=1}^n s_i^p)^{1/p}$ .

- (3) Obviously, the  $L_p$  norms (Minkowski distances) also follow from Euclidean volume because a  $p$ -dimensional volume can only be equal to the sum of other  $p$ -dimensional volumes:  $\forall V \in \mathbb{R}^p \exists v_1, \dots, v_n \in \mathbb{R}^p : V = \sum_{i=1}^n v_i \Rightarrow \forall d^p = V \exists s_1, \dots, s_n \in \mathbb{R} : d^p = \sum_{i=1}^n s_i^p \Rightarrow d = (\sum_{i=1}^n s_i^p)^{1/p}$ .
- (4) The smallest possible countable distance (3.1),  $d_c = |\bigcup_{i=1}^n y_i|$ , is the case of the largest intersection of the range sets, which is also the case of the largest possible number (the Cartesian product) of domain-to-range set mappings, in flat space:  $d_c = f(\sum_{i=1}^n |x_i| \cdot |y_i|) = f(\sum_{i=1}^n p_i^2)$ . And applying the ruler to create countable sets of subintervals of domain and range intervals, the Cartesian product of domain-to-range set mappings yields the Euclidean distance equation.
- (5) Manhattan (largest) distance and Euclidean (largest) volume are both cases of disjoint range sets,  $\bigcap_{i=1}^n y_i = \emptyset$ , in flat space (where  $|x_i| = |y_i|$ ):

$$d_c = |\bigcup_{i=1}^n y_i| : \bigcap_{i=1}^n x_i = \bigcap_{i=1}^n y_i = \emptyset \quad \wedge \quad |x_i| = |y_i|.$$

$$v_c = |\times_{i=1}^n y_i| : \bigcap_{i=1}^n x_i = \bigcap_{i=1}^n y_i = \emptyset \quad \wedge \quad |x_i| = |y_i|.$$

- (6) Applying the volume proof (4.2) to the Cartesian product of same-sized, infinitesimal mass forces and charge forces to derive Newton's gravity force (5.1) and Coulomb's charge force (5.2) equations provide several firsts and several insights into physics.
- (a) The first deductive derivations. All other derivations have been empirical and inductive (not fully provable).
- (b) The first derivations not using the inverse square law, or Gauss's divergence theorem.
- (c) The first derivations to show that time is proportionate to distance ( $r = (r_c/t_c)t = ct$ ), which is then used to derive the spacetime equations (5.3) without the notion of the speed of light.
- (d) The first derivations to show that all Euclidean distance intervals having a size,  $r$ , have proportionately sized intervals of other types:  $r = (r_c/q_C)q = (r_c/m_G)m = (r_c/t_c)t = ct$ , which allows much simpler derivations of some general relativity equations (5.4) without the need for vectors and tensors.
- (e) The first derivations to show that the definition of force,  $F := ma$ , containing acceleration,  $a = r/t_c^2$ , and combined with  $r = (r_c/t_c)t$ , generates the inverse square law:  

$$F = m_0 a = m_0 r / t_c^2 = (r_c / t_c)^2 (m_x r_c / x_x^2) x_1 x_2 / r^2 = k_x x_1 x_2 / r^2.$$
- (f) Some constants like charge, vacuum magnetic permeability, fine structure, etc. contain the value  $4\pi$  because the creators assumed that the inverse square law was due to Gauss's flux divergence on the surface of a sphere having the area,  $4\pi r^2$ . But, the derivations of the gravity and charge force equations show that the inverse square law is the result of the definition of force containing acceleration. Therefore, those versions of the constants containing the value  $4\pi$  are incorrect.
- (g) Multiple proportion ratios (constant first derivatives) with respect to the same distance,  $r_c$ , raises the question whether the related ratios can create quantum values for mass and charge.

- (h) If there are quantum values of mass,  $m_G$ , and charge,  $q_C$ , then there is a quantum distance,  $r_c$ , where the gravity and charge forces do not exist (are not defined) at smaller distances.
  - (i) Discrete, state values have no proportion ratio to varying distance and time interval lengths. For example, the change of spin values of two quantum entangled electrons and the change of polarization of two quantum entangled photons are independent of the distance and time between the entangled particles.
- (7) It was proved that a totally ordered set with a symmetry constraint is a cyclic set with at most 3 members (5.3). And the definitions of distance and volume both require a total order and symmetry, which provides several insights.
- (a) Using Occam's razor, a cyclic set of at most 3 members is the most parsimonious explanation of only observing 3 dimensions of distance and volume.
  - (b) If there are higher dimensions of ordered and symmetric geometric space, then there is a set of three members (5.4), each member being an ordered and symmetric set of 3 dimensions (three balls), yielding a total of 9 ordered and symmetric dimensions of geometric space.
  - (c) Each ordered and symmetric ball can have at most 3 ordered and symmetric dimensions of discrete states of the same type, for example, a set of 3 binary values, 1 and -1, indicating vector orientation.
  - (d) Each dimension of discrete physical states can have at most 3 ordered and symmetric discrete state values, which allows  $3 \cdot 3 \cdot 3 = 27$  possible combinations of discrete values of the same type per ball, for example, spin values: -1, 0, 1 per orthogonal plane in the ball.
  - (e) Each of the 3 possible ordered and symmetric dimensions of discrete physical states could contain an unordered collection (bag) of discrete state values. Bags are non-deterministic. For example, every time an unordered binary state is pulled from a bag, there is a 50 percent chance of getting one of the binary values.
